This non-invasive imaging modality finds widespread application in ophthalmology for assessing retinal structures and diagnosing diseases like glaucoma and macular degeneration. The handbook details the principles of OCT, different types of OCT systems (e.g., time-domain, spectral-domain), and advanced applications like optical biopsy and intravascular imaging. Understanding the intricacies of OCT, as detailed within the handbook, is crucial for researchers and clinicians working in this area.

Fluorescence Spectroscopy

Fluorescence spectroscopy uses the emission of light from fluorescent molecules to analyze the composition and structure of biological samples. This technique, comprehensively discussed in the monograph, allows for highly sensitive detection of various biomarkers, offering valuable insights into disease processes. Applications range from cancer diagnostics to the detection of infectious agents. The handbook provides a detailed explanation of the fundamental principles, experimental setup, and data analysis methods involved in fluorescence spectroscopy.

Laser-Induced Breakdown Spectroscopy (LIBS)

LIBS, another important technique described within the handbook, uses laser-induced plasma to analyze the elemental composition of biological samples. This technique is particularly useful for identifying trace elements and for real-time, in-situ analysis. LIBS is gaining traction in applications such as cancer diagnostics and forensic science. The monograph provides an in-depth understanding of LIBS principles, instrumentation, and data interpretation strategies.
