FAQ

Q1: What is the difference between network analysis and network synthesis?

A1: Network analysis focuses on understanding the properties and behavior of existing networks. It involves analyzing network structure, identifying critical nodes, and predicting network behavior. Network synthesis, on the other hand, focuses on designing new networks with specific properties and functionalities. It involves selecting components, defining interconnections, and optimizing the network design to meet specific performance goals. Mohan's work touches upon both aspects, offering tools for both analyzing existing networks and creating new ones.

Q2: What are some of the limitations of current network analysis techniques?

A2: Current techniques can struggle with the scale and complexity of many real-world networks. Analyzing massive datasets efficiently remains a challenge. Additionally, many techniques assume static networks, while many real-world networks are dynamic and evolving. Furthermore, accurately modeling the interactions and dependencies within complex systems can be difficult. Mohan's work addresses some of these limitations through the development and application of advanced optimization techniques.

Q3: How can network analysis help in improving the resilience of critical infrastructure?

A3: By identifying critical nodes and bottlenecks, network analysis can help prioritize investments in infrastructure improvements to enhance resilience. Understanding the vulnerability of the network to various types of failures (e.g., cascading failures) allows for the development of mitigation strategies. Mohan's research on network topology and optimization directly contributes to this crucial area.

Q4: What role does graph theory play in network analysis?
