FAQ

Q1: What is the main difference between ion exchange and solvent extraction?

A1: Ion exchange involves the reversible exchange of ions between a solid phase (resin) and a liquid phase (solution). Solvent extraction involves the transfer of a solute from one liquid phase (aqueous) to another immiscible liquid phase (organic) based on differences in solubility. Ion exchange is primarily used for separating charged species, while solvent extraction is more versatile and can separate both charged and neutral species.

Q2: What are the advantages of using combined ion exchange and solvent extraction?

A2: Combining these techniques often results in synergistic effects. For example, solvent extraction can pre-concentrate a target analyte before ion exchange purifies it further. This leads to increased efficiency, selectivity, and reduced costs compared to using either technique alone.

Q3: What are some limitations of ion exchange and solvent extraction?

A3: Ion exchange resins can be susceptible to fouling and degradation, reducing their lifespan and efficiency. Solvent extraction can generate hazardous waste if

inappropriate solvents are used. Both techniques can be energy-intensive, particularly for large-scale applications.
